

Summary

In a device for screwing caps onto containers with several closing heads revolving on a closed track, each of which [closing heads] has a controllable gripping tong, a control unit for the opening position and the closed position of the corresponding gripping tong, which revolves along with this, is allocated to every gripping tong. The revolving control units can be reversed in direction between the opening position and the closed position by means of stationary stops. By this means, a precise and rapid reversal of the gripping tongs, as well as a simple adjustment of the opening- and closed position, is made possible without a stationary control curve.
